

1.5 Polynomial Notes

Polynomial Function: Let n be a nonnegative integer and let $a_n, a_{n-1}, \dots, a_2, a_1, a_0$ be real numbers with $a_n \neq 0$. The function given by

$$f(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_2 x^2 + a_1 x + a_0$$

Is called a polynomial function in x of degree n .

Graphs: We read graphs from left to right.

Leading Coefficient	What does the graph do
Odd and positive	<p>Starts in bottom left and raises to right.</p> 
Odd and negative	<p>Starts in the upper left and drops right</p> 
Even and positive	<p>Both ends go up</p> 
Even and negative	<p>Both ends go down</p> 

Real Zeros of Polynomial Functions

If f is a polynomial function and a is a real number, the following statements are equivalent.

1. $x = a$ is a zero of the function f .
2. $x = a$ is a solution of the polynomial equation $f(x) = 0$.
3. $(x - a)$ is a factor of the polynomial $f(x)$.
4. $(a, 0)$ is an x-intercept of the graph of f .

Find Zeros of a Polynomial Function

Example:

Find all real zeros of $f(x) = x^3 - x^2 - 2x$

1. Set equal to zero. $0 = x^3 - x^2 - 2x$
2. Factor an x. $0 = x(x^2 - x - 2)$
3. Factor the quadratic. $0 = x(x - 2)(x + 1)$
4. Solve for x. $x = 0, 2, -1$
5. Check work.

Repeated Zeros: For a polynomial function, a factor of $(x - a)^k$, $k > 1$, yields a repeated zero $x = a$ of multiplicity k.

1. If k is odd, the graph crosses the x-axis at $x = a$.
2. If k is even, the graph touches the x-axis (but does not cross the x-axis) at $x = a$.

Long Division of Polynomials

Divide $6x^3 - 19x^2 + 16x - 4$ by $x - 2$, and use the result to factor the polynomial completely.

Solution

$$\begin{array}{r}
 \begin{array}{c} \text{Partial quotients} \\ \downarrow \quad \downarrow \quad \downarrow \\ 6x^2 - 7x + 2 \end{array} \\
 x - 2 \overline{) 6x^3 - 19x^2 + 16x - 4} \\
 \underline{6x^3 - 12x^2} \qquad \text{Multiply: } 6x^2(x - 2). \\
 - 7x^2 + 16x \qquad \text{Subtract.} \\
 \underline{- 7x^2 + 14x} \qquad \text{Multiply: } -7x(x - 2). \\
 2x - 4 \qquad \text{Subtract.} \\
 \underline{2x - 4} \qquad \text{Multiply: } 2(x - 2). \\
 0 \qquad \text{Subtract.}
 \end{array}$$

$$f(x) = (x - 2)(2x - 1)(3x - 2), \quad x = 2, \frac{1}{2}, \frac{2}{3}$$

Sometimes, long division will produce a nonzero remainder.

Example: $x^2 + 3x + 5$ by $x + 1$

$$\begin{array}{r}
 \text{Divisor} \quad \rightarrow \quad x + 1 \overline{) x^2 + 3x + 5} \quad \leftarrow \text{Quotient} \\
 \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \leftarrow \text{Dividend} \\
 \qquad \qquad \qquad \qquad \underline{x^2 + x} \\
 \qquad \qquad \qquad \qquad \qquad \qquad \qquad 2x + 5 \\
 \qquad \qquad \qquad \qquad \underline{2x + 2} \\
 \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad 3 \quad \leftarrow \text{Remainder}
 \end{array}$$

In fractional form, you can write this result as follows.

$$\begin{array}{c}
 \text{Dividend} \\
 \overbrace{x^2 + 3x + 5} \\
 \underbrace{x + 1} \\
 \text{Divisor}
 \end{array}
 =
 \begin{array}{c}
 \text{Quotient} \\
 x + 2
 \end{array}
 +
 \begin{array}{c}
 \text{Remainder} \\
 \downarrow \\
 \frac{3}{\underbrace{x + 1}} \\
 \text{Divisor}
 \end{array}$$

Synthetic Division:

Synthetic Division (of a Cubic Polynomial)

To divide $ax^3 + bx^2 + cx + d$ by $x - k$, use the following pattern.

Use synthetic division to divide $x^4 - 10x^2 - 2x + 4$ by $x + 3$

Solution

You should set up the array as follows. Note that a zero is included for each missing term in the dividend.

Then, use the synthetic division pattern by adding terms in columns and multiplying the results by -3 .

$$\begin{array}{r|rrrrr}
 -3 & 1 & 0 & -10 & -2 & 4 \\
 & & -3 & 9 & 3 & -3 \\
 \hline
 & 1 & -3 & -1 & 1 & 1
 \end{array}$$

Divisor: $x + 3$ Dividend: $x^4 - 10x^2 - 2x + 4$

Quotient: $x^3 - 3x^2 - x + 1$ Remainder: 1

So, you have

$$\frac{x^4 - 10x^2 - 2x + 4}{x + 3} = x^3 - 3x^2 - x + 1 + \frac{1}{x + 3}$$

The Rational Zero Test

If the polynomial

$$f(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_2 x^2 + a_1 x + a_0$$

Has integer coefficients, every rational zero of f has the form

$$\text{Rational zero} = \frac{p}{q}$$

Where p and q have no common factors other than 1, p is a factor of the constant term a_0 and q is a factor of the leading coefficient a_n .

Example: Find the rational zeros of $f(x) = 2x^3 + 3x^2 - 8x + 3$

$$\begin{aligned}
 p &= 2 \text{ and } q = 3 \\
 \text{Possible Rational Zeros} &= \frac{\text{factors of } 3}{\text{factors of } 2} = \pm 1, \pm 3, \pm \frac{1}{2}, \pm \frac{3}{2}
 \end{aligned}$$

By synthetic division, you can determine that $x = 1$ is a rational zero.

$$\begin{array}{r|rrrr} 1 & 2 & 3 & -8 & 3 \\ & & 2 & 5 & -3 \\ \hline & 2 & 5 & -3 & 0 \end{array}$$

So, $f(x)$ factors as

$$f(x) = (x - 1)(2x^2 + 5x - 3) = (x - 1)(2x - 1)(x + 3)$$
